

Class Design

Mārtiņš Leitass

Objectives

- Define *inheritance, polymorphism, overloading, overriding, and virtual method invocation*
- Use the access modifiers `protected` and the default (*package-friendly*)
- Describe the concepts of constructor and method overloading
- Describe the complete object construction and initialization operation

Subclassing

The Employee class is shown here.

Employee
+name : String = ""
+salary : double
+birthDate : Date
+getDetails() : String

```
public class Employee {  
    public String name = "";  
    public double salary;  
    public Date birthDate;  
  
    public String getDetails() {...}  
}
```

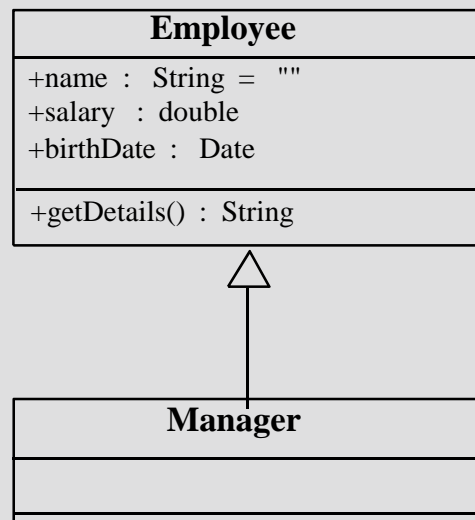

Subclassing

The Manager class is shown here.

Manager
+name : String = "" +salary : double +birthDate : Date +department : String
+getDetails() : String

```
public class Manager {  
    public String name = "";  
    public double salary;  
    public Date birthDate;  
    public String department;  
  
    public String getDetails() {...}  
}
```

Class Diagrams for Employee and Manager Using Inheritance

```
public class Employee {
    public String name = "";
    public double salary;
    public Date birthDate;

    public String getDetails() {...}
}
```

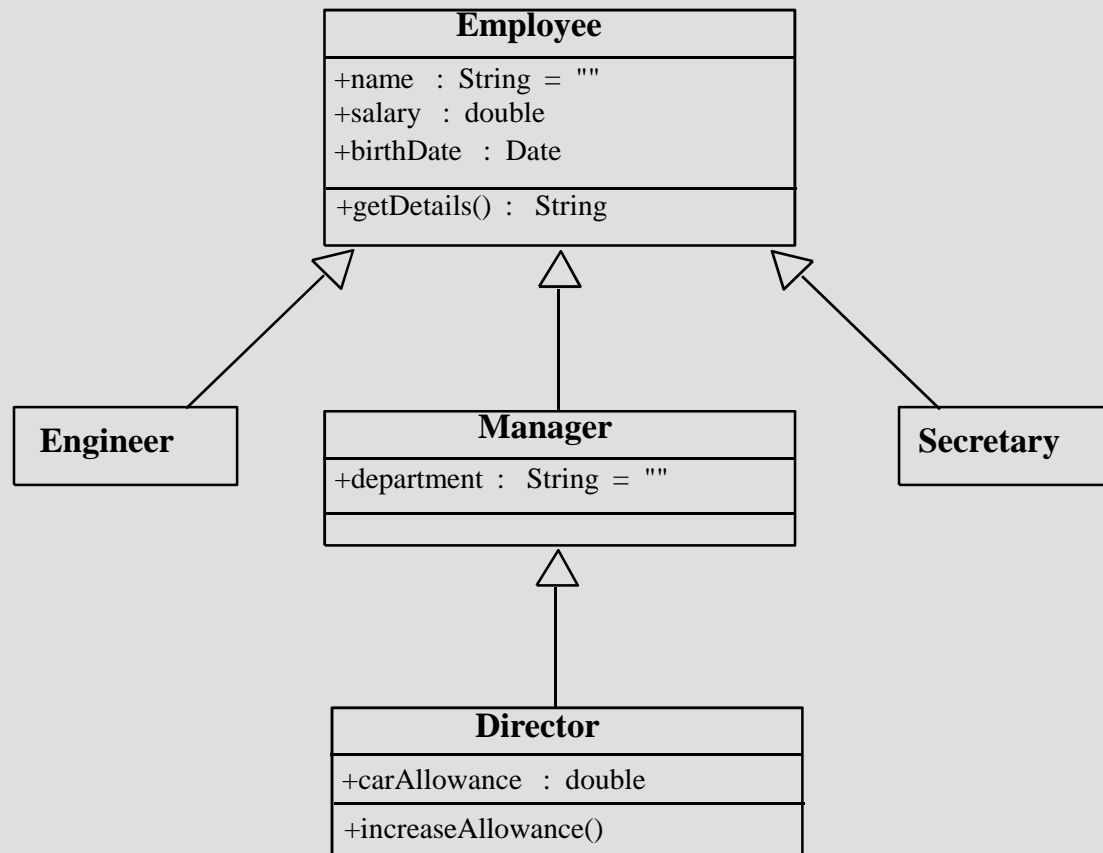

```
public class Manager extends Employee {
    public String department;
}
```

Single Inheritance

- When a class inherits from only one class, it is called *single inheritance*.
- *Interfaces* provide the benefits of multiple inheritance without drawbacks.
- Syntax of a Java class is as follows:

```
<modifier> class <name> [extends <superclass>] {  
    <declaration>*  
}
```

Single Inheritance

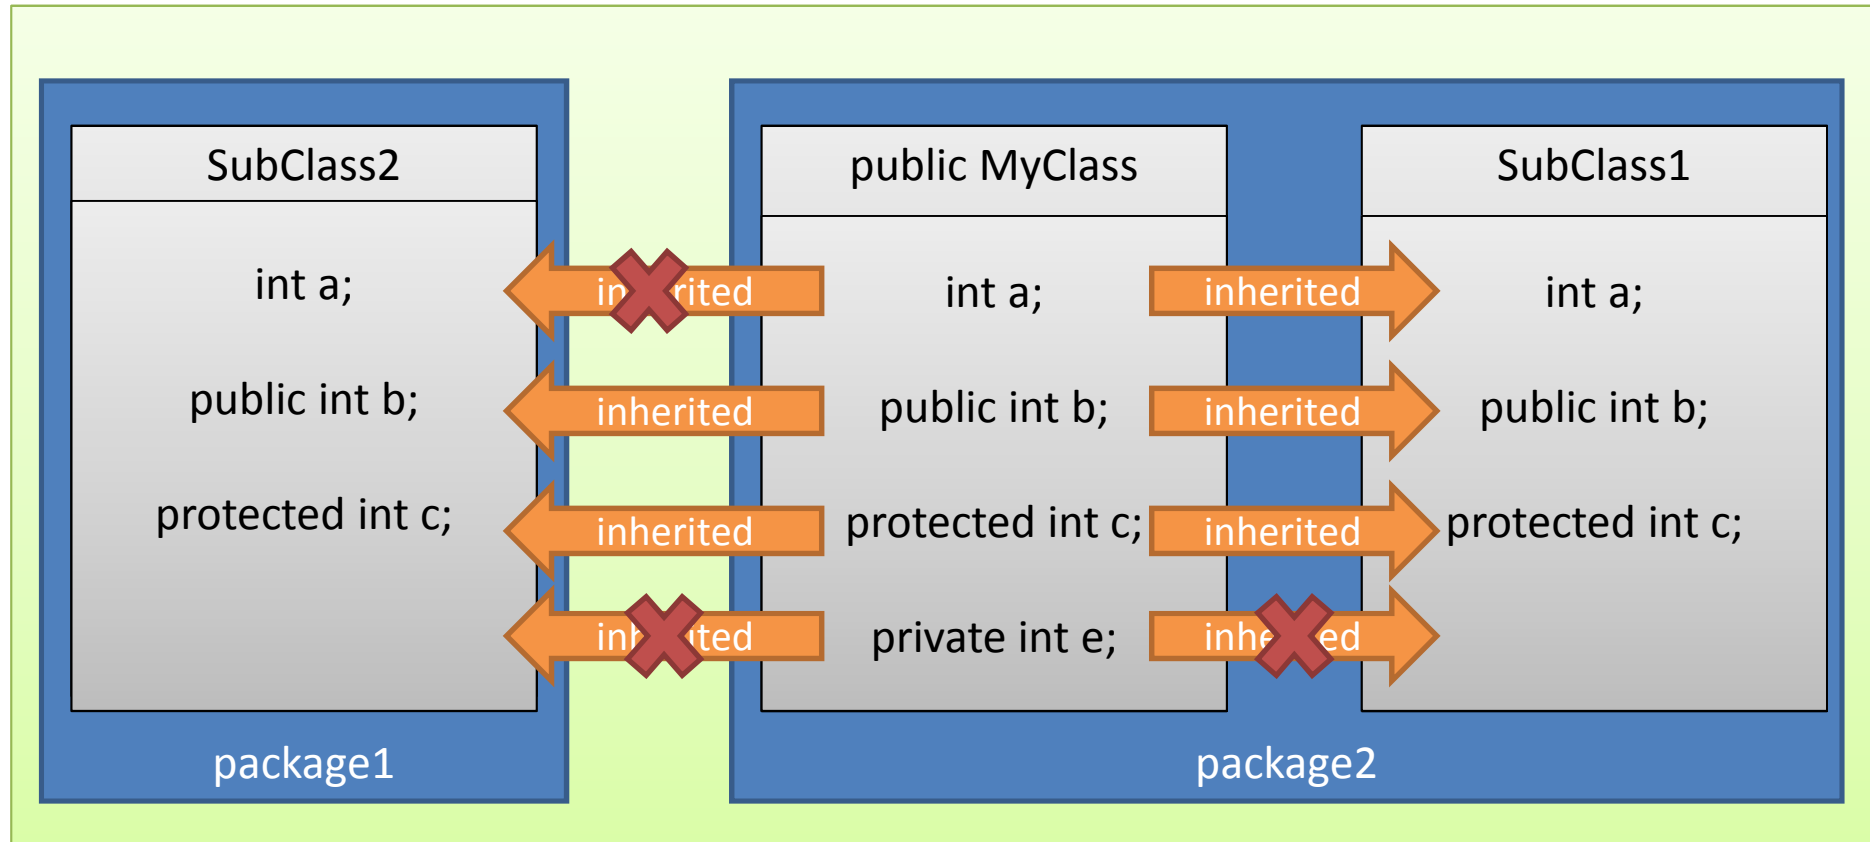

Access Control

Access modifiers on class member declarations are listed here.

Modifier	Same Class	Same Package	Subclass	Universe
private	Yes			
default	Yes	Yes		
protected	Yes	Yes	Yes	
public	Yes	Yes	Yes	Yes

Inheriting Data Members

Overriding Methods

- A subclass can modify behavior inherited from a parent class.
- A subclass can create a method with different functionality than the parent's method but with the same:
 - Name
 - Return type¹
 - Argument list

1. In J2SE version 5, the return type can be a subclass of the overridden return type.

Overriding Methods

```
1 public class Employee {
2     protected String name;
3     protected double salary;
4     protected Date birthDate;
5
6     public String getDetails() {
7         return "Name: " + name + "\n" +
8             "Salary: " + salary;
9     }
10 }

1 public class Manager extends Employee {
2     protected String department;
3
4     public String getDetails() {
5         return "Name: " + name + "\n" +
6             "Salary: " + salary + "\n" +
7             "Manager of: " + department;
8     }
9 }
```

Overridden Methods Cannot Be Less Accessible

```
1 public class Parent {  
2     public void doSomething() {}  
3 }
```

```
1 public class Child extends Parent {  
2     private void doSomething() {} // illegal  
3 }
```

```
1 public class UseBoth {  
2     public void doOtherThing() {  
3         Parent p1 = new Parent();  
4         Parent p2 = new Child();  
5         p1.doSomething();  
6         p2.doSomething();  
7     }  
8 }
```

Invoking Overridden Methods

A subclass method may invoke a superclass method using the `super` keyword:

- The keyword `super` is used in a class to refer to its superclass.
- The keyword `super` is used to refer to the members of superclass, both data attributes and methods.
- Behavior invoked does not have to be in the superclass; it can be further up in the hierarchy.

Invoking Overridden Methods

```
1 public class Employee {  
2     private String name;  
3     private double salary;  
4     private Date birthDate;  
5  
6     public String getDetails() {  
7         return "Name: " + name + "\nSalary: " + salary;  
8     }  
9 }
```

```
1 public class Manager extends Employee {  
2     private String department;  
3  
4     public String getDetails() {  
5         // call parent method  
6         return super.getDetails()  
7             + "\nDepartment: " + department;  
8     }  
9 }
```

Polymorphism

- *Polymorphism* is the ability to have many different forms; for example, the Manager class has access to methods from Employee class.
- An object has only one form.
- A reference variable can refer to objects of different forms.

Polymorphism

```
Employee e = new Manager(); // legal
```

```
// illegal attempt to assign Manager attribute
```

```
e.department = "Sales";
```

```
// the variable is declared as an Employee type,
```

```
// even though the Manager object has that attribute
```

Virtual Method Invocation

- Virtual method invocation is performed as follows:

```
Employee e = new Manager();  
e.getDetails();
```

- Compile-time type and runtime type invocations have the following characteristics:
 - The method name must be a member of the declared variable type; in this case Employee has a method called getDetails.
 - The method implementation used is based on the runtime object's type; in this case the Manager class has an implementation of the getDetails method.

Heterogeneous Collections

- Collections of objects with the same class type are called *homogeneous* collections. For example:

```
MyDate[]  dates = new MyDate[2];  
dates[0] = new MyDate(22, 12, 1964);  
dates[1] = new MyDate(22, 7, 1964);
```

- Collections of objects with different class types are called *heterogeneous* collections. For example:

```
Employee [] staff = new Employee[1024];  
staff[0]      = new Manager();  
staff[1]      = new Employee();  
staff[2]      = new Engineer();
```

Polymorphic Arguments

Because a Manager is an Employee, the following is valid:

```
public class TaxService {  
    public TaxRate findTaxRate(Employee e) {  
        // calculate the employee's tax rate  
    }  
}
```

```
// Meanwhile, elsewhere in the application class  
TaxService taxSvc = new TaxService();  
Manager m = new Manager();  
TaxRate t = taxSvc.findTaxRate(m);
```

The instanceof Operator

```
public class Employee extends Object
public class Manager extends Employee
public class Engineer extends Employee
```

```
public void doSomething(Employee e) {
    if ( e instanceof Manager ) {
        // Process a Manager
    } else if ( e instanceof Engineer ) {
        // Process an Engineer
    } else {
        // Process any other type of Employee
    }
}
```

Casting Objects

```
public void doSomething(Employee e) {  
    if ( e instanceof Manager ) {  
        Manager m = (Manager) e;  
        System.out.println( "This is the manager of "  
                             + m.getDepartment());  
    }  
    // rest of operation  
}
```

Casting Objects

- Use `instanceof` to test the type of an object.
- Restore full functionality of an object by casting.
- Check for proper casting using the following guidelines:
 - Casts *upward* in the hierarchy are done implicitly.
 - *Downward* casts must be to a subclass and checked by the compiler.
 - The object type is checked at runtime when runtime errors can occur.

Overloading Methods

- Method overloading is the declaring of method with same name as another method in the same class, but with different arguments.
- Use overloading as follows:

```
public void println(int i)
public void println(float f)
public void println(String s)
```

- Argument lists *must* differ.
- Return types *can* be different.
- Method Signature:

A method signature is made up of the method *name* and *parameter list* (it does not include the return type) it is illegal for a class to declare two methods with the same signature

Methods Using Variable Arguments

- Methods using *variable arguments* permit multiple number of arguments in methods.

For example:

```
public class Statistics {  
    public float average(int... nums) {  
        int sum = 0;  
        for ( int x : nums ) {  
            sum += x;  
        }  
        return ((float) sum) / nums.length;  
    }  
}
```

- The *vararg* parameter is treated as an array. For example:

```
float gradePointAverage = stats.average(4, 3, 4);  
float averageAge = stats.average(24, 32, 27, 18);
```

Overloading Constructors

- As with methods, constructors can be overloaded.

An example is:

```
public Employee(String name, double salary, Date DoB)
public Employee(String name, double salary)
public Employee(String name, Date DoB)
```

- Argument lists *must* differ.
- You can use the `this` reference at the first line of a constructor to call another constructor.

Overloading Constructors

```
1  public class Employee {
2      private static final double BASE_SALARY = 15000.00;
3      private String name;
4      private double salary;
5      private Date    birthDate;
6
7      public Employee(String name, double salary, Date DoB) {
8          this.name = name;
9          this.salary = salary;
10         this.birthDate = DoB;
11     }
12     public Employee(String name, double salary) {
13         this(name, salary, null);
14     }
15     public Employee(String name, Date DoB) {
16         this(name, BASE_SALARY, DoB);
17     }
18     // more Employee code...
19 }
```

Constructors Are Not Inherited

- A subclass inherits all methods and variables from the superclass (parent class).
- A subclass does not inherit the constructor from the superclass.
- Two ways to include a constructor are:
 - Use the default constructor.
 - Write one or more explicit constructors.

Invoking Parent Class Constructors

- To invoke a parent constructor, you must place a call to `super` in the first line of the constructor.
- You can call a specific parent constructor by the arguments that you use in the call to `super`.
- If no `this` or `super` call is used in a constructor, then the compiler adds an implicit call to `super()` that calls the parent no argument constructor (which could be the *default* constructor).

If the parent class defines constructors, but does not provide a no-argument constructor, then a compiler error message is issued.

Invoking Parent Class Constructors

```
1 public class Manager extends Employee {
2     private String department;
3
4     public Manager(String name, double salary, String dept) {
5         super(name, salary);
6         department = dept;
7     }
8     public Manager(String name, String dept) {
9         super(name);
10        department = dept;
11    }
12    public Manager(String dept) { // This code fails: no super()
13        department = dept;
14    }
15    //more Manager code...
16 }
```

Constructing and Initializing Objects: A Slight Reprise

Memory is allocated and default initialization occurs.

Instance variable initialization uses these steps recursively:

1. Bind constructor parameters.
2. If explicit `this()`, call recursively, and then skip to Step 5.
3. Call recursively the implicit or explicit super call, except for `Object`.
4. Execute the explicit instance variable initializers.
5. Execute the body of the current constructor.

Constructor and Initialization Examples

```
1 public class Object {  
2     public Object() {}  
3 }
```

```
1 public class Employee extends Object {  
2     private String name;  
3     private double salary = 15000.00;  
4     private Date    birthDate;  
5  
6     public Employee(String n, Date DoB) {  
7         // implicit super();  
8         name = n;  
9         birthDate = DoB;  
10    }  
11    public Employee(String n) {  
12        this(n, null);  
13    }  
14 }
```

```
1 public class Manager extends Employee {  
2     private String department;  
3  
4     public Manager(String n, String d) {  
5         super(n);  
6         department = d;  
7     }  
8 }
```

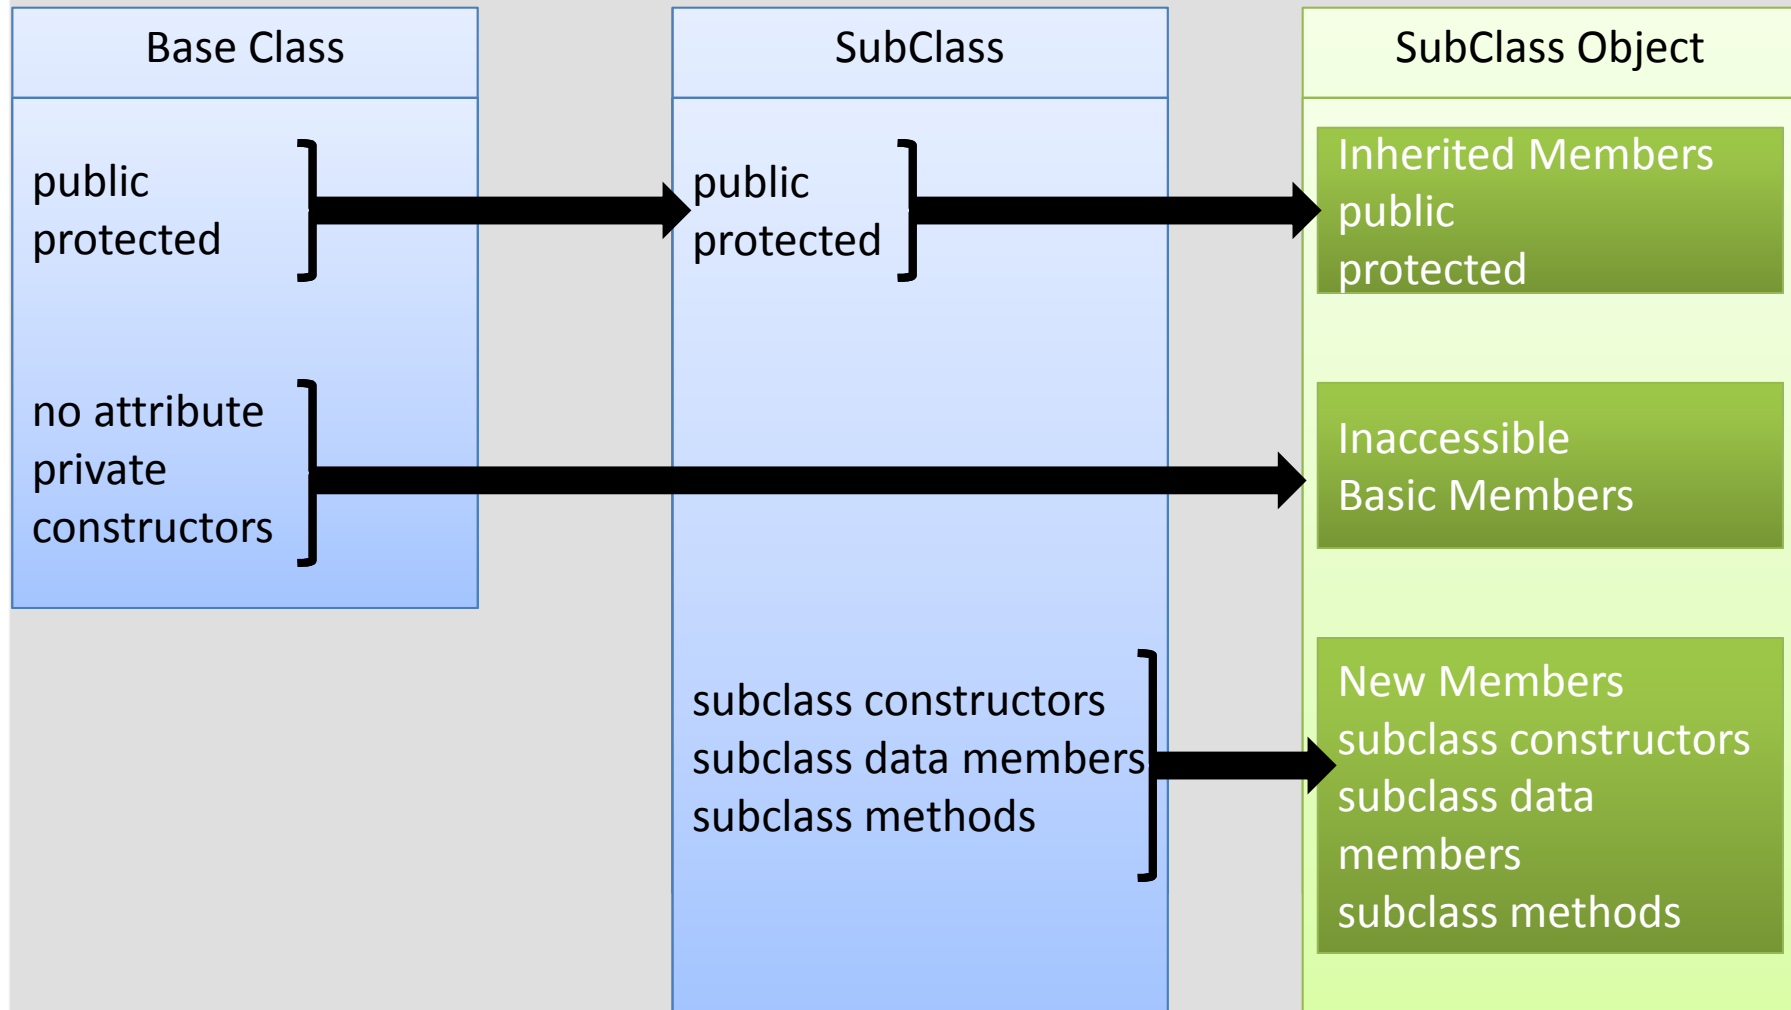

Constructor and Initialization Examples

- 0 Basic initialization
 - 0.1 Allocate memory for the complete Manager object
 - 0.2 Initialize all instance variables to their default values (0 or null)
- 1 Call constructor: Manager("Joe Smith", "Sales")
 - 1.1 Bind constructor parameters: n="Joe Smith", d="Sales"
 - 1.2 No explicit this() call
 - 1.3 Call super(n) for Employee(String)
 - 1.3.1 Bind constructor parameters: n="Joe Smith"
 - 1.3.2 Call this(n, null) for Employee(String, Date)
 - 1.3.2.1 Bind constructor parameters: n="Joe Smith", DoB=null
 - 1.3.2.2 No explicit this() call
 - 1.3.2.3 Call super() for Object()
 - 1.3.2.3.1 No binding necessary
 - 1.3.2.3.2 No this() call
 - 1.3.2.3.3 No super() call (Object is the root)
 - 1.3.2.3.4 No explicit variable initialization for Object
 - 1.3.2.3.5 No method body to call

Constructor and Initialization Examples

- 1.3.2.4 Initialize explicit Employee variables: salary=15000.00;
- 1.3.2.5 Execute body: name="Joe Smith"; date=null;
- 1.3.3 - 1.3.4 Steps skipped
- 1.3.5 Execute body: No body in Employee(String)
- 1.4 No explicit initializers for Manager
- 1.5 Execute body: department="Sales"

Objects of a Derived Class

The ObjectClass

- The Object class is the root of all classes in Java.
- A class declaration with no `extends` clause implies `extends Object`. For example:

```
public class Employee {  
    ...  
}
```

is equivalent to:

```
public class Employee extends Object {  
    ...  
}
```

- Two important methods are:
 - `equals`
 - `toString`

The equalsMethod

- The `==` operator determines if two references are identical to each other (that is, refer to the same object).
- The `equals` method determines if objects are *equal* but not necessarily identical.
- The `Object` implementation of the `equals` method uses the `==` operator.
- User classes can override the `equals` method to implement a domain-specific test for equality.
- Note: You should override the `hashCode` method if you override the `equals` method.

An equals Example

```
1  public class MyDate {  
2      private int day;  
3      private int month;  
4      private int year;  
5  
6      public MyDate(int day, int month, int year) {  
7          this.day    = day;  
8          this.month  = month;  
9          this.year   = year;  
10     }
```

An equals Example

```
11
12  public boolean equals(Object o) {
13      boolean result = false;
14      if ( (o != null) && (o instanceof MyDate) ) {
15          MyDate d = (MyDate) o;
16          if ( (day == d.day) && (month == d.month)
17              && (year == d.year) ) {
18              result = true;
19          }
20      }
21      return result;
22  }
23
24  public int hashCode() {
25      return (day ^ month ^ year);
26  }
27
```

An equals Example

```
1  class TestEquals {  
2      public static void main(String[] args) {  
3          MyDate date1 = new MyDate(14, 3, 1976);  
4          MyDate date2 = new MyDate(14, 3, 1976);  
5  
6          if ( date1 == date2 ) {  
7              System.out.println("date1 is identical to date2");  
8          } else {  
9              System.out.println("date1 is not identical to date2");  
10         }  
11  
12         if ( date1.equals(date2) ) {  
13             System.out.println("date1 is equal to date2");  
14         } else {  
15             System.out.println("date1 is not equal to date2");  
16         }  
17     }  
18 }
```

An equals Example

```
17
18     System.out.println("set date2 = date1;");
19     date2 = date1;
20
21     if ( date1 == date2 ) {
22         System.out.println("date1 is identical to date2");
23     } else {
24         System.out.println("date1 is not identical to date2");
25     }
26
27
```

This example generates the following output:

```
date1 is not identical to date2
date1 is equal to date2
set date2 = date1;
date1 is identical to date2
```

String class object Equality

- literal strings will represent the **same reference** if they are created
 - in the same class and in the same package
 - in different classes within the same package
 - in different classes in different packages
 - using constant expressions computed at compile time
 - by explicitly using the **intern()** method and the resulting string is already in the string pool
- literal strings will represent **different references** if they are newly created at runtime

String objects and references - questions

```
String str1 = "Lions and Tigers and  
Bears!";
```

```
String str2 = "Lions and Tigers and  
Bears!";
```

```
String str3 = str2;
```

```
String str4 = new String("Lions and  
Tigers and Bears!");
```

```
String str5 = " Oh my!";
```

```
String str6 = "Lions and Tigers and  
Bears! Oh my!";
```

```
String str7 = str1 + str5;
```

```
String str8 = (str1 + " Oh  
my!").intern();
```

- `str1 == str2` ?
 - true the str2 literal existed ("interned")
- `str1 == str3` ?
 - true hold the same reference
- `str1 == str4` ?
 - false str4 explicitly created
- `str2 == str3` ?
 - true hold the same reference
- `str2 == str4` ?
 - false str4 explicitly created
- `str3 == str4` ?
 - false str4 explicitly created
- `str6 == str7` ?
 - false str7 computed at runtime
- `str6 == str8` ?
 - true explicit use of `intern()` at runtime

The toStringMethod

The toString method has the following characteristics:

- This method converts an object to a String.
- Use this method during string concatenation.
- Override this method to provide information about a user-defined object in readable format.
- Use the wrapper class's toString static method to convert primitive types to a String.

Wrapper Classes

Look at primitive data elements as objects.

Primitive Data Type

boolean

byte

char

short

int

long

float

double

Wrapper Class

Boolean

Byte

Character

Short

Integer

Long

Float

Double

Wrapper Classes

An example of a wrapper class is:

```
int pInt = 420;  
Integer wInt = new Integer(pInt); // this is called boxing  
int p2 = wInt.intValue(); // this is called unboxing
```

Other methods are:

```
int x = Integer.valueOf(str).intValue();  
int x = Integer.parseInt(str);
```

Autoboxing of Primitive Types

Autoboxing has the following description:

- Conversion of primitive types to the object equivalent
- Wrapper classes not always needed
- Example:

```
int pInt = 420;  
Integer wInt = pInt; // this is called autoboxing  
int p2 = wInt; // this is called autounboxing
```

- Language feature used most often when dealing with collections
- Wrapped primitives also usable in arithmetic expressions
- Performance loss when using autoboxing

Jautājums?

```
public class One{
    public double getResult(int value){
        return (double) 10*value;
    }
}
public class Two extends One{
    public double getResult(int value){
        return (double) 5*value;
    }
}
public static void main(String args[]){
    One x = new Two();
    double y = x.getResult(2);
    System.out.println(y);//?
}
```

Design Hints for Inheritance

- Place common operations and fields in the superclass
- Use inheritance to model the "is-a" relationship
- Don't change the expected behavior when you override a method
